Nickeliferous Ores.
Mine la Motte, Madison County, Mo.

Historical and Descriptive.

The Mine la Motte property consists of a tract of about 24000 acres situated in the counties of Madison and St. Francois, principally in the former, however.

It has been worked since the year 1720, and besides its historical interest is certainly one of the most important mines in the state, as regards both the capitalist and scientist.

These facts warrant a detailed description of the mines, and the methods of working which are in vogue there, these being necessary to any one who ^{would} realize their magnitude and importance.

The property is situated about 100 miles Southeast of St. Louis on the Iron Mountain Railroad. The principal mining is done at the village of Mine la Motte, three miles east of Mine la Motte station. The deposits of Nickel and Cobalt found here are the most extensive now known and operated in the United States, and yield a very large proportion of the total production of those metals in the world.

Historical and Descriptive.

The Mine la Motte property consists of a tract of about 24000 acres situated in the counties of Madison and St. Francois, principally in the former, however. It has been worked since the year 1720, and besides its historical interest is certainly one of the most important mines in the state, as regards both the capitalist and scientist. These facts warrant a detailed description of the mines, and the methods of working which are in vogue there, these being necessary to any one who would realize their magnitude and importance. The property is situated about 100 miles Southeast of St. Louis on the Iron Mountain Railroad. The principal mining is done at the village of Mine la Motte, three miles east of Mine la Motte station. The deposit of Nickel and Cobalt found here are the most extensive now known and operated in the United States, and yield a very large proportion of the total production of those metals in the world.

The Diggings.

The chief points at which the mining is carried on

are at the "Bluff Diggings," the "Jack Diggings," and the "Seed-tick Diggings." The "Bluff" and "Jack" Diggings are about one mile apart, and are separated by a ridge running South east, and North west. At the "Jack Diggings" more than five acres of rock have been excavated, the mining being mostly confined to one immense chamber, the vault being supported by stone columns, either left when mining or built up afterward of the refuse material.

Mining.

The mining is done in the ordinary way, proper to horizontal bedded deposits. About 170 miners are kept continually at work removing the ore.

Analyses of specimens of the crude ore gave the following results:

Specimen of raw ore from Seed Tick Diggings:

Copper,	13.319%
Zinc,	0.020"
Nickel,	0.233"
Iron,	<u>13.517"</u>
Total foreign metals	27.089"

This particular specimen was somewhat remarkable for the large amount of copper and Iron it contained.

are at the "Bluff Diggings," the "Jack Diggings," and the "Seed-tick Diggings." The "Bluff" and "Jack" Diggings are about one mile apart, and are separated by a ridge running South east, and North west. At the "Jack Diggings" more than five acres of rock have been excavated, the mining being mostly confined to one immense chamber, the vault being supported by stone columns, either left when mining or built up afterward of the refuse material.

Mining.

The mining is done in the ordinary way, proper to horizontal bedded deposits. About 170 miners are kept continually at work removing the ore.

Analyses of specimens of the crude ore gave the following results:

Specimen of raw ore from Seed Tick Diggings:

Copper,	13.319%
Zinc,	0.020"
Nickel,	0.233"
Iron,	<u>13.517"</u>
Total foreign metals	27.089"

This particular specimen was somewhat remarkable for the large amount of copper and Iron it contained.

A specimen of raw ore from the "Bluff Diggings" gave the following result:

Zinc,	0.040%
Nickel,	0.214 "
Iron,	<u>2.529 "</u>
Total foreign metals,	2.783 "

Washing and Dressing the Ore.

The ores are transported from the mines to the dressing-works in small cars running on tramways, and capable of carrying from 4000 to 10000 pounds of ore.

Crushing: The ore is crushed, first in a Blake's Breaker capable of crushing from 25 to 30 cars per day of 24 hours or an average of about 175000 lbs. The crushed ore is now passed through rollers and then through circular sieves, the coarser particles from which pass into the elevator, and again through rollers now set more closely together, and this is repeated until all passes through the sieve. The sieved ore now passes into the Jigs which wash off the light particles, and divides the ore into two classes: "Smiddam" or coarser, and Sludge or finer. The following are the results obtained upon analysis of specimens of the two grades of washed ore:

<u>Smiddam (coarse)</u>	
Copper	0.103%
Cobalt	0.042 "
Nickel	0.575 "
Iron	<u>1.435 "</u>
Total	2.155 "

This residue is now passed to treatment in the cupola with a part of the previously roasted ore.

The Cupola furnaces.

Dimensions of the circular cupola:

Diameter of furnace, 3 feet.

Height of charging plate above tuyeres - 12 feet.

" " tuyeres above hearth plate - 8 inches.

Thickness of the lining 21 inches.

A shift lasts 12 hours and requires 5 men to the shift.

Dimensions of the square cupola:

Thickness of wall 2.5 feet.

Height of tuyeres above hearth-plate - 11 inches

" " furnace above tuyeres - 11 feet.

No. of tuyeres - 3; diameter of nozzle - $2\frac{5}{8}$ inches

Pressure of blast, about 10 oz of mercury.

The method of treating the ore is the same in both cupolas and consists in charging the pulverized and roasted ore, coke and flux in alternate layers. The flux used is a hematite obtained from Iron Mountain. Its composition is as under:

Ferric oxide = 94.545%

Alumina — 3.922 "

Magnesia — 0.401 "

Lime — 0.129 "

Silica — 1.182 "

Total — 100.179

This residue is now passed to treatment in the cupola with a part of the previously roasted ore.
